Economic concerns appear to be weak predictors of white political identity*

Damon C. Roberts 

University of Colorado Boulder

damon.roberts-1@colorado.edu

ABSTRACT Do economic or political threats explain reported white identity? Overall, the social identity literature would suggest that white identity would increase in response to economic threats. However, a number of those that study white identity, specifically, argue that it results from concern about political influence. Considering what whiteness means historically and contemporaneously, I argue that we should expect that political threats reflect stronger associations with white identity. Using data from the 2012, 2016, and 2020 American National Election Study, I consider a single model using penalized regression containing proxies of economic and political threats. I find evidence suggesting that in the post-Trump era, white political identity is strongly associated with reported feelings of Whites' loss of political influence as opposed to economic threats, as some suggest and may expect.

KEYWORDS white identity; economic threat; cultural threat

*Word count (including references): 3655. I would like to thank Jennifer Wolak for her feedback on the many drafts of this manuscript. I would also like to thank the Keller Center for the First Amendment for the research appointment that gave me the space to work on the early stages of this project. I would also like to thank Anand Sokhey and John Griffin for their advice and suggestions in the early drafts of this paper. I would also like to thank Tabitha Bonilla, Nicole Yadon, and participants and audience members of a Midwestern Political Science Association panel for which an earlier draft this idea was presented. I would also like to thank Tamar Malloy, Andrew Philips, Kathryn Schauer, Rachel O'Neal, Alexander Jensen, Komal Kaur, Andrew Engelhardt, and Madeline Mader for their encouragement and feedback at various stages of this project's development. All errors contained in this manuscript are ultimately mine.

Introduction

Do economic or political threats motivate the expression of a racial identity among Whites in politics? The existing work offers an unclear answer to this question. This note provides an omnibus test to determine not only which of these questions has more empirical support but also which among common proxies of economic and political power in the United States appear to be reliable predictors of a White individual's expression of racial identity.

As the American National Election Study is a long-running survey of Americans', it provides some of the most consistent measures on common political attitudes and behaviors. Using data from the 2012, 2016, and 2020 administrations of the ANES, I fit an omnibus model with penalized regression to examine the degree to which individual measures of economic and political influence explain an individual's uptake of White identity as well as to examine the degree to which changes in the political context may increase or decrease the explanatory power of these measures. From this test, I find that proxies reporting concerns about Whites' political influence are stronger explanatory factors than proxies of economic influence in the post-Trump era.

Identity and white political identity

One perspective on what explains racial identity among Whites in the United States are that they are responding to threats to their economic status and power. Realistic Conflict Theory suggests that a racial identity and racial prejudice come as a response to a collective concern among members of a particular racial group about the loss of economic influence and

status a group holds relative to other racial groups (Blumer 1958; Bobo and Hutchings 1996). Some evidence suggests that Whites living in areas with shrinking job opportunities respond to this with an increased desire to protect the interests of their racial confederates (Baccini and Weymouth 2021). Others have experimental evidence supporting this perspective that White identity is motivated by material concerns (Pérez et al. 2022). Further, Jardina (2019) who provides one of the most comprehensive treatments of conceptualizing, measuring, and examining the outcomes of White identity in politics includes indicators of economic status and power in the primary model.

Social identity theory, and its offshoots, would suggest an alternative perspective: that Whites expressing a racial identity are responding to political, cultural, and societal threats. While these threats are a bit more hard to define, there are a number of examples that demonstrate Whites are responsive to cultural or political changes that present as a threat. For example, Mutz (2018) finds little support for the claim that the 2016 Presidential Election – which support for Trump is associated with an expression of racial identity among Whites (Jardina 2020) – was a response to the economic effects of a globalizing economy and instead argues that it was a response to concerns about the changes brought about by globalization and the racial-diversity it promotes. Others demonstrate that the behavioral manifestations of a White constituency in the United States was a reflection of the saliency of race in politics (Agadjanian and Lacy 2021). A final example demonstrated that exposure to a story about discrimination about a White person lead individuals concerned with the racial hierarchy to report that Whites faced similar amounts of institutional racism as Blacks (Marshburn, Reinkensmeyer, and Knowles 2022). Others have made similar arguments through historical lenses by arguing that while race and class are highly correlated, the saliency of race in

society and in our institutions continue to make it a salient group by which we structure our thinking about who has status and power (Helms and Carter 1990; Dawson 1994; Rile Hayward 2013). This perspective fits with many arguments that the United States is not as class-conscious as they are race-conscious (Zoltan L. Hajnal 2020).

Political versus economic threats

I am using a popular conceptualization of racial identity among Whites: that expression of it reflects homophily toward's one's own racial group (Ellemers, Spears, and Doosje 2002; Jardina 2019). As identity conceptualized this way may predict negative intergroup attitudes, it reflects a desire to find ways to find similarities rather than differences between one's self and other in-group members (Ellemers, Spears, and Doosje 2002). Identity is largely an elusive concept to operationalize (see Leach et al. 2008). Though there are implicit measures of White identity (see Knowles and Peng 2005), the common and measure of white identity is a response to the question, "How important is being White to your identity?" This measure captures a significant feature of an identity: the centrality or the importance of that identity to an individual (Jardina 2019). Though a rather rough measure of something as complex as identity, it has been shown to produce similar results to more complex measures of white identity and holds a significant amount of face validity (Jardina 2019).

Threat is also quite difficult to measure directly. However, we can make a number of reasonable guesses about who may feel economic and political threat. There are two key things that threats affect. Status and power. Status refers to the respectability of the group whereas power refers to the influence that the group has (Craig and Phillips 2023).

Threat here refers to either a manifestation of economic or political challenges to the current racial hierarchy. I do not distinguish between these two sources of threat as common survey measures are too crude to distinguish between how the threat manifests. Here, I am focusing on what types of non-material threats activate White identity in the context of politics and will, as a shorthand refer to political, cultural, and societal threats as political threats.

A reasonable approach to measuring economic threat is to measure the economic circumstances that White individuals find themselves in. We may expect that Whites who are facing bottom-up economic competition, will be those that experience the strongest desire to identify themselves with their racial group. As the dominant racial group in the United States, Whites that are unemployed, are surrounded by other Whites who are experiencing economic hardship and those who have limited capacity to switch careers are those that may be the most motivated to identify with the dominant racial group to defend Whites' influence and status in society (Bobo and Hutchings 1996). Therefore, measures of employment, finances, family finances, finances of those they know, and educational attainment all seem likely predictors of racial identity for Whites. This fits with measures that Dawson (1994) used to measure the influence of economics in Black American's identity. These measures also fit with Lindsay (2023) who found that many of these items predicted racial resentment among Whites.

Here I conceptualize of political threat as perceptions that politics and political institutions no longer serves White people. Existing work demonstrates that Whites who express a desire to maintain the racial status quo with Whites on top are more likely to express that Whites are discriminated against at similar levels as Blacks (Marshburn, Reinkensmeyer, and Knowles 2022). As Whiteness is often a central component of Whites' conceptualization of

American society (see [Green and Staerklé 2013](#)), changes to “traditional American values” may reflect concern about changes to the influences of White values. Finally, a common finding is that expression of White identity is heavily wrapped up in the perception that racial stratifications are by meritocratic means ([Lowery et al. 2012](#)). As members of a dominant social group, when given information that either threatens one’s belief that their merits are earned or that their group operates as a way to maintain inequality, we expect lower levels of expression in identification with that group. The classic items of racial resentment construct capture these ideas in that they revolve around the idea that Blacks are not disadvantaged as the result of systematic oppression by Whites. Though many have often used racial resentment as a measure of prejudice which would be a possible outcome of White identity, some make the compelling argument that it is distinct as a concept and operationalization ([Davis and Wilson 2022](#)).

Data

To examine whether whites’ attitudes expressing concern about political threats are more robust correlates than their perceptions of the economy, I use the 2012, 2016, and 2020 American National Election Studies (ANES). The studies are nationally representative questions that capture several questions that lend themselves to testing the relationship between economic and political concerns while also asking white respondents to report how important being white is to their identity.

Though I am using the more crude measure of White identity and am limited in the predictors I can choose from, a larger concern is that the degree to which these threats

may vary as a result of changes to the political landscape. Specifically, in 2008 the United States experienced a massive recession that lead hit the housing market quite hard. In 2012, the economy was still recovering. In 2016, Donald Trump became infamous for an election where he made race and gender extremely salient (Banda and Cassese 2022). Finally, in 2020, Trump had been in office for four years with an improving economy. Each of these three years reflect a different context and may offer the opportunity to observe how economic and political threats operate differently.

Question wording for each of the items in the following models are included in Table 1 which is located in the Supplementary Materials. I include descriptive statistics for the measures in these samples in Table 2, Table 3, and Table 4 located in the Supplementary Information.

Evidence from a penalized regression

The primary contribution of this paper is to examine which, of several competing measures, of different types of threat may predict white identity for individuals. As this requires an omnibus test, I elect to use a penalized regression. I provide a more detailed discussion of the reasons why I use an estimator with an L2 regularization parameter, often referred to as a LASSO model in the supplementary materials. In practice, the model applies a penalization term so predictors that have relatively fewer explanatory power have much smaller coefficients than the variables that do provide significant predictive power.

My measure of white identity is ordinal. Therefore, I apply a ordered logistic link function. Though it creates a more complicated computational task, it is a more appropriate model

specification given the available measure and my assumptions about the concept (Liddell and Kruschke 2018).

To account for potential problems stemming from missing data, I impute my data by using multiple imputation with chained equations (MICE) where the particular model I use is a random forest model to allow for more flexibility and to reduce model dependence (Buuren and Groothuis-Oudshoorn 2011; Marbach 2022).¹ I report the results of the model fitted using listwise deletion in the Supplementary Information.

Results

Figure 1 presents the estimates of my fitted ordinal models with the LASSO shrinkage prior.² These models are fit on 6 chains with 2000 iterations each. To examine the evidence of whether a particular predictor “matters” for predicting white political identity, I examine the estimated credible intervals, which report the probability that the true estimate falls within the estimated range. I construct these credible intervals by reporting estimates between the 2.5% and 97.5% quantiles. This means that for a given credible interval, there is a two-tailed 95% probability that the true value falls within that range. For values outside the range of the credible interval, it is relatively implausible that the given value is the true value.

Examining the figure, we see that none of the proxies for economic threat consistently correlate with White political identity; however there is at least one proxy of political threat that does. For economic threats, we see that when the economy was recovering from the

¹I impute 10 datasets and simultaneously fit my Bayesian LASSO on each dataset and pool the results. Uncertainty reflected in my reported credible intervals not only reflects the uncertainty from one model, but my reported uncertainty also reflects the uncertainty generated from the imputation procedure. One drawback with this particular approach is that my normalized split- \hat{R} will likely be greater than the widely recognized 1.01 cutoff that indicates model convergence due to the pooling of my multiply imputed datasets.

²The full tables of results are included in the Supplementary Information.

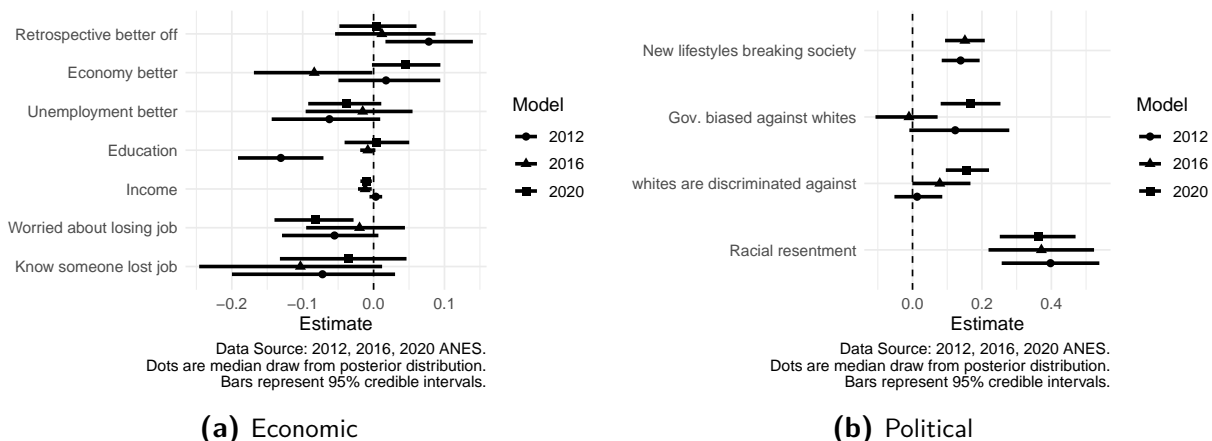

Figure 1: Economic factors are weak predictors of white identity

recession and Obama was in Office, those who perceived that the economy was better off retrospectively and with a lower reported level of education were correlated with expressing a higher White identity. However, when the economy was better and Trump was in office, we see that those less worried about losing a job were reported a higher white identity.

For political threats, we see that in both instances where Obama was in the White House that those who reported being concerned with “new lifestyles” as well as those with a higher score on the racial resentment measures were associated with having higher white political identities. When Trump was in the White House, we see that those who felt that the government was biased against Whites, that Whites were discriminated against, and who scored higher on the racial resentment measures all reported higher levels of White political identity.

An additional question worth examining is that economic or political threat may appear differently for partisans and for female respondents. Recent evidence suggests that racial attitudes are guided by partisanship (Engelhardt 2021). Specifically, some evidence suggests that White Democrats are much more sensitive to their racial identity than White Repub-

licans due to the higher amount of racial heterogeneity within the Democratic party. This may mean for White Democrats that they have more exposure to intergroup competition for power within the party (such as the choice to support Hillary Clinton versus Barack Obama) and may have higher White identification as a result. The second way that these threats may matter more or less for Whites is on the dimension of sex. Sex-based differences in economic influence and status remains quite high. We therefore may expect that female individuals are more sensitive to economic threats than their male counterparts. In addition to the omnibus model, I also include two additional models where I split the samples along the dimension of partisanship (including leaners in each) and on the dimension of sex.

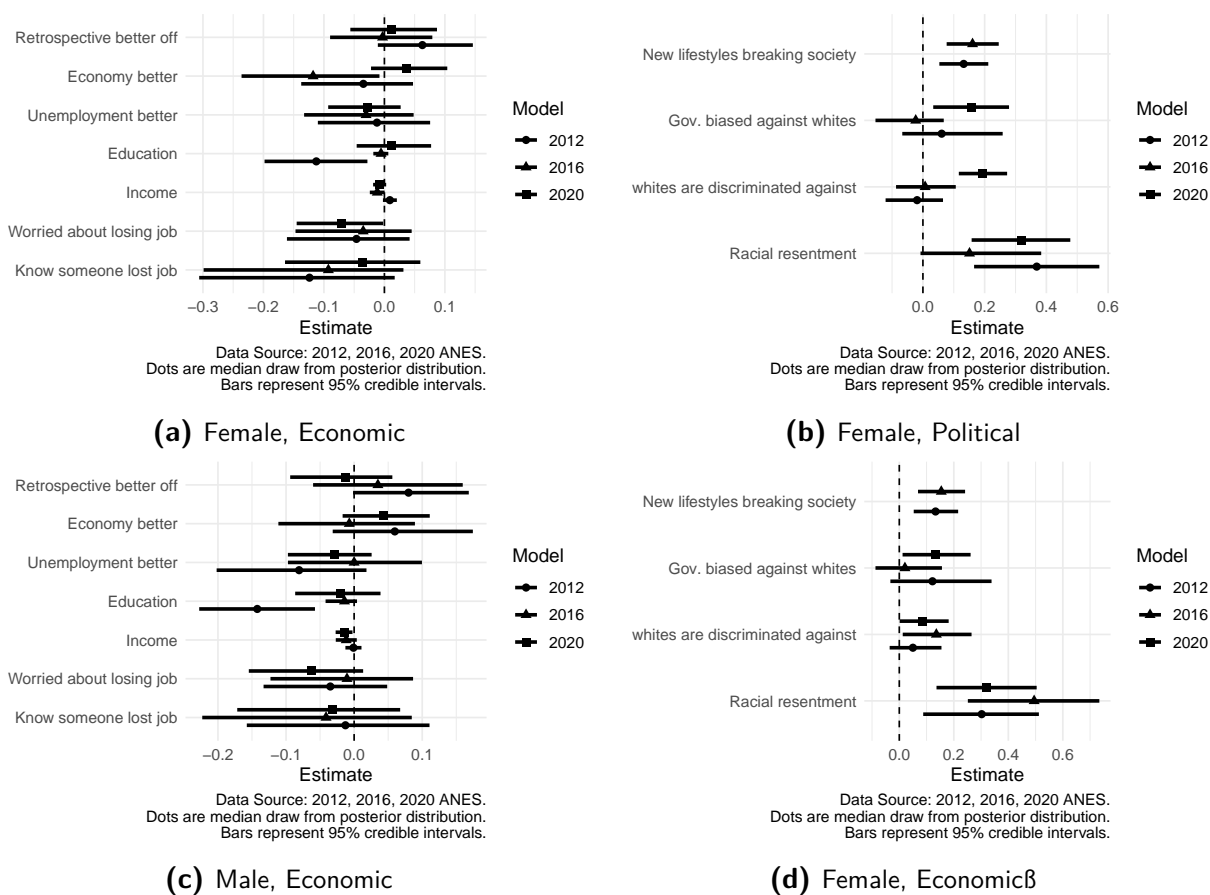

Figure 2: Economic factors are weak predictors of white identity

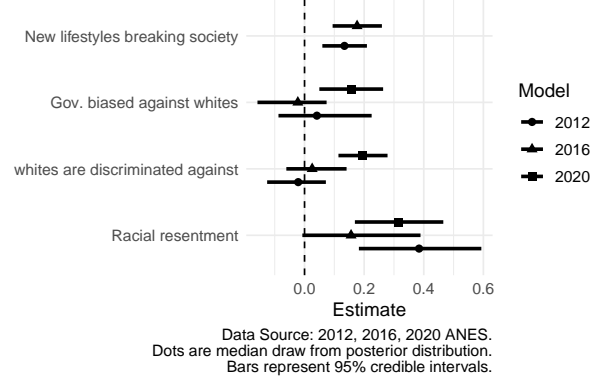

(a) Republican, Economic

(b) Republican, Political

(c) Democrat, Economic

(d) Democrat, Political

Figure 3: Economic factors are weak predictors of white identity

We see in both Figure 2 and Figure 3 that indicators of economic and political threat do not have much substantial variation between male and female respondents and Republican and Democrat respondents. The full table of results for the model are included in Table 6, Table 9, Table 12, Table 7, Table 10, and Table 13 in the Supplementary Materials.

Discussion and conclusions

Overall, these results suggest that common proxies of economic threat are at least inconsistent measures of White identity. Even in a time where the economy is recovering from a collapse, more proxies of political threat seemed to predict White identity. When a White president well-known for his penchant for racial dog-whistles takes office, we see support for the idea that White grievance politics was at a high as evidenced by those who felt that political institutions and that the direction of society was turning away from the racial status quo were those that reported their racial identity as more central to who they are.

There are a few important points that are illustrated here. First, suggestions that White political identity is something occurring for those who are most economically threatened appear to have weak theoretical and empirical backing when directly pitted against symbolic forms of threat. Second, when thinking about what is driving racial identity among Whites, evidence from this omnibus test suggests that it is more symbolic forms of threat as opposed to material.

These findings provide a direction for scholars to take when examining the factors driving Whites to take on a white political identity. While this particular analysis is not causal,

it provides a basis for those wondering whether, when put together, economic or political threats are more fruitful to engender a rise in white political identity.

Model

The literature surveyed above suggests that there are a small number of variables that do predict white political identity, and there are many others that have no effect. Imagining an assumed hypothesis about the distribution of coefficients, this implies that the L2 regularization parameter equals 0. This is because the L2 regularization parameter shrinks coefficients asymptotically toward zero. The L1 regularization parameter, however, does allow for a shrinkage parameter to pull coefficients to 0. Given this, it suggests that the more appropriate model to capture this debate would be the LASSO penalized regression.

Rather than use the classical LASSO with Leave One Out Cross Validation (LOOCV), I take advantage of a type of Markov Chain Monte Carlos (MCMC) called a Hamiltonian Monte Carlo for my LASSO due to a number of benefits outlined by Erp, Oberski, and Mulder (2019). As the literature leads me to hold *a priori* expectations about the distribution of predictors that meaningfully effect white political identity, I specify a Laplace distribution as my prior density function. I suspect that there are a large number of included predictors that have null effects and a relatively smaller proportion of predictors that *do* have an effect but am relatively unsure about how large their coefficients might be. This characterization of my prior fits with that of an L2 Shrinkage parameter specified in a LASSO regression. As I am not using LOOCV, I am able to interpret the results of the model through my credible intervals.
